Abstract
In this article, an applied matrix method, which is based on Bernoulli Polynomials, has been presented to find approximate solutions of high order Volterra integro-differential equations. Through utilizing this approach, the proposed equations reduce to a system of algebraic equations with unknown Bernoulli coefficients. A comparison of Bernoulli matrix method solutions with the results of the other numerical methods has been carried out, which shows that the Bernoulli matrix metod solutions are more accurate in comparison with the other methods.

Keywords: Integro-differential equations, Bernoulli polynomials, Operational matrix.

Introduction
Integro-differential equations are a adaptable mathematical implement for symbolizing physical problems. A review of the related literature reveals that, they have been very popular among researchers in the mathematical modelling of physical phenomenon as gravitation, electrostatics, etc. It is also famous that initial-value and boundary-value problems of differential equations can often be converted into integral equations and there are usually considerable advantages employing this conversion. Among these equations, Volterra integro-differential equations is derived from various applications, like engineering, biology, etc (see [8], [11] and the references therein).

Polynomial series have gained significant attention in dealing with various problems of differential, integral and integro-differential equations. Since polynomials can easily be defined, they are very useful mathematical tools which can be calculated quickly on computer systems and represent a great variety of functions. It is rather easy to differentiate

*Corresponding author: m.matinfar@umz.ac.ir
and integrate them, and they can be pieced together to form spline curves that can precisely approximate any function. Also, the main feature of this method technique is that it reduces complex problems to those simpler problems of solving a system of algebraic equations, thus they can greatly simplify the problems.

Bernoulli polynomials play a main role in a variety of expansions and approximation formulas. These formulas can be very useful not only in analytic theory of numbers, but also in classical and numerical analysis. The Bernoulli polynomials and numbers have been generalized by Norlund [18] to the Bernoulli polynomials and numbers of higher order. Also, Vandiver in [24] generalized the Bernoulli numbers. Analogous polynomials and sets of numbers have been defined from time to time, witness the Euler polynomials and numbers and the so-called Bernoulli polynomials of the second kind. These polynomials can be defined by various methods [13], [14], [15], [12], [20], [17].

This paper concerns the following high order Volterra integro-differential equation in the form

\[ \sum_{j=0}^{m} c_j y^j(x) = f(x) + \int_0^x k(x, s) y(s) \, ds, \quad 0 \leq x < 1 \]

with initial condition \( y^j(0) = a_j, \quad j=0,1,\ldots, m-1. \)

where, \( y(x) \) and \( f(x) \) are continuous differentiability functions of the desired order

and \( k(x,s) \) is a continuous differentiability of the desired order and separable kernel and \( c_j \)'s are constant coefficients and \( y^j(x) = \frac{d^j}{dx^j} y(x). \)

This article is classified as follows: in section 2, we have presented the elementary possessions of the Bernoulli polynomials. Section 3 is applied to the approximation of functions by Bernoulli polynomials. In section 4, operational matrix is presented. In section 5, the process of the method is explained and in section 6 convergence of method is analysed. Finally, in section 7 a comparison of the numerical solutions is made with some exact or approximate solutions in order to assess the precision of the suggested method.

### Bernoulli Polynomials

The Bernoulli polynomials of order \( m \), are defined in [12] by

\[ B_m(x) = \sum_{k=0}^{m} \binom{m}{k} b_k x^{m-k}, \quad (2) \]
Numerical Approximation Based on the Bernoulli Polynomials for Solving Volterra Integro-Differential of High Order

where, $\beta_k$, \( k = 0, 1, \ldots, m \) are Bernoulli numbers. These numbers are a sequence of signed rational numbers, which are obtained from the series expansion of trigonometric functions [3] and can be defined by

$$\frac{t}{e^t-1} = \sum_{n=0}^{\infty} \frac{\beta_n}{n!} t^n.$$  

The first few Bernoulli numbers are

$$\beta_0 = 1, \quad \beta_1 = -\frac{1}{2}, \quad \beta_2 = \frac{1}{6}, \quad \beta_4 = \frac{-1}{30},$$

with $\beta_{2k+1} = 0, \ k = 1, 2, 3, \ldots$ The first few Bernoulli Polynomials are

$$B_0(x) = 1, \quad B_1(x) = x - \frac{1}{2}, \quad B_2(x) = x^2 - x + \frac{1}{6}, \quad B_3(x) = x^3 - \frac{3}{2} x^2 + \frac{1}{2} x,$$

The following properties apply Bernoulli Polynomials [7,16]

$$B_m(0) = \beta_m, \quad m \geq 0$$  \hspace{1cm} (3)

$$\int_a^x B_m(t) dt = \frac{B_{m+1}(x) - B_{m+1}(a)}{m+1},$$  \hspace{1cm} (4)

$$\int_0^1 B_n(t) B_m(t) dt = (-1)^{n-1} \frac{m! n!}{(m+n)!}, m, n \geq 1$$  \hspace{1cm} (5)

$$\sum_{k=0}^{n} B_k(t) = (n+1)t^n$$  \hspace{1cm} (6)

It can be easily illustrated that any given polynomial of degree $n$ can be expanded with regard to linear combination of the basis function

$$p(x) = \sum_{i=0}^{n} c_i B_i(x) = C^TB(x)$$

where $C$ and $B(x)$ are $(n+1) \times 1$ vectors given by

$$C = [c_0, c_1, \ldots, c_n]^T, \quad B(x) = [B_0(x), B_1(x), \ldots, B_n(x)]^T$$  \hspace{1cm} (7)

for each $i = 0, 1, \ldots, n$ the following matrix form can be obtained:

$$B_i(x) = \begin{pmatrix} i \end{pmatrix} B_i + \begin{pmatrix} i \end{pmatrix} B_{i-1}x + \cdots + \begin{pmatrix} i \end{pmatrix} B_1 x^{i-1} + \begin{pmatrix} i \end{pmatrix} B_0 x^i,$$

then

$$B_i(x) = M_i T(x),$$  \hspace{1cm} (8)

where $T(x) = [1 \ x \ x^2 \ \ldots \ x^n]^T$, and

$$M_i = \begin{pmatrix} i \end{pmatrix} B_i \begin{pmatrix} i \end{pmatrix} B_{i-1} \begin{pmatrix} i \end{pmatrix} B_{i-2} \cdots \begin{pmatrix} i \end{pmatrix} B_1 \begin{pmatrix} i \end{pmatrix} B_0.$$  

Now, we can expand the matrix $B(x)$ as

$$B(x) = [B_0(x), B_1(x), \ldots, B_n(x)]^T = [M_0 T(x), M_1 T(x), \ldots, M_n T(x)]^T$$
\[ \begin{bmatrix} M_0, M_1, \ldots, M_n \end{bmatrix}^T T(x) = \begin{bmatrix} B_0 & 0 & 0 & \ldots & 0 \\ \frac{1}{1!} B_1 & \frac{1}{0!} B_0 & 0 & \ldots & 0 \\ \frac{2}{2!} B_2 & \frac{2}{1!} B_1 & \frac{2}{0!} B_0 & 0 & \ldots \\ \frac{3}{3!} B_3 & \frac{3}{2!} B_2 & \frac{3}{1!} B_1 & \frac{3}{0!} B_0 & 0 \vdots \\ \frac{n}{n!} B_n & \frac{n}{(n-1)!} B_{n-1} & \frac{n}{(n-2)!} B_{n-2} & \frac{n}{(n-3)!} B_{n-3} & \ldots & \frac{1}{0!} B_0 \end{bmatrix} T(x) \]

then, we have

\[ B(x) = M T(x), \quad (9) \]

where \( M \) is a lower triangular \((n+1)(n+1)\) matrix and \( \det(M) = 1 \), so \( M \) is an invertible matrix.

On the other hand by using Eq. (6), we have

\[ \sum_{k=0}^{n+1} B_k(x) = (n+1)x^n, \]

\[ QB(x) = T(x) \Rightarrow B(x) = Q^{-1} T(x), \quad (10) \]

where \( Q \) is a lower triangular \((n+1)(n+1)\) matrix and \( \det(Q) = 1 \), so \( Q \) is an invertible matrix.

Then from (9), (10), we have

\[ Q^{-1} = M. \]

**Approximation of functions**

Suppose that \( H = L^2[0,1] \) and \( \{B_0(x), B_1(x), \ldots, B_N(x)\} \subset H \) be the set of Bernoulli polynomials and

\[ Y = \text{span} \{B_0(x), B_1(x), \ldots, B_N(x)\} \]

and \( f \) be any member in \( H \). Since \( Y \) is a finite dimensional vector space, \( f \) has the unique best approximation out of \( Y \) such as \( \hat{f} \), that is

\[ \forall y \in Y, \quad \|f - \hat{f}\| \leq \|f - y\|. \]

Since \( \hat{f} \in Y \), there exists the unique coefficients \( f_0, f_1, \ldots, f_N \) such that

\[ f \approx \hat{f} = \sum_{n=0}^{N} f_n B_n(x) = F^T B(x) \]

\[ (11) \]
which
\[ B^T(x) = [B_0(x), B_1(x), ..., B_N(x)], F^T = [f_0, f_1, ..., f_n] \]

**Corollary 3.1.** Suppose that \( f \) be an arbitrary function and also is approximated by the truncated Bernoulli series as \( \sum_{i=0}^{N} f_i B_i(x) \) then the coefficients \( f_i \) can be computed from the following formula
\[ f_i = \int_0^1 f^{(i)}(x) dx, \quad (12) \]
which \( i = 1, ..., N \).

**Corollary 3.2.** Suppose that \( K(x, s) \in H \times H = L^2[0,1] \times L^2[0,1] \) be an arbitrary function and also is approximated by the two variable truncated Bernoulli series
\[ \sum_{m=0}^{N} \sum_{n=0}^{N} k_{m,n} B_m(x) B_n(s), \]
then the coefficients \( k_{m,n} \) can be computed from the following relation
\[ k_{m,n} = \frac{1}{m! n!} \int_0^1 \int_0^1 \frac{\partial^{m+n} K(x,s)}{\partial x^m \partial s^n} dx ds, \quad m, n = 0, 1, ..., N \quad (13) \]
or
\[ K(x,s) \simeq B^T(x)K B(s), \quad (14) \]
which \( K = (k_{m,n})_{(N+1) \times (N+1)} \), \( m, n = 0,1,...,N \).

**Operational matrix of integration**

**Theorem 4.1.** For integration of the vector \( B(t) \) defined in Eq. (11) we have the following formula
\[ \int_0^x B(t) dt \simeq PB(x) \quad (15) \]
which \( P \) is the \( (N + 1) \times (N + 1) \) operational matrix of integration, which \( P = UQ \) where
\[ U = [U_1, U_2, ..., U_n, \Xi^T M]^T \]
where
\[ U_i = [0 \quad \frac{1}{i} \left( \begin{array}{c} i \\ i - 1 \end{array} \right) B_{i-1} \quad \frac{1}{i} \left( \begin{array}{c} i \\ i - 2 \end{array} \right) B_{i-2} \quad ... \quad \frac{1}{i} \left( \begin{array}{c} i \\ 1 \end{array} \right) B_1 \quad \frac{1}{i} B_0 \quad ...] \]
and \( \Xi = [c_1, c_2, ..., c_n]^T \) which \( \frac{B_{N+1}(x)-B_N}{N+1} \approx \Xi^T B(x) \), \( \Xi \) can be obtained by (12).
The operational matrix of integration, $P$, is a sparse matrix, which is one of the advantages of using Bernoulli polynomials for solving equations. For example, for $N=3$, $P$ is

$$
\begin{bmatrix}
\frac{1}{2} & 1 & 0 & 0 \\
-1 & 0 & 1 & 0 \\
\frac{1}{12} & 0 & \frac{1}{2} & 0 \\
0 & 0 & 0 & \frac{1}{3} \\
\frac{1}{120} & 0 & \frac{1}{14} & 0 \\
\end{bmatrix}
$$

And, it can be seen by computing the operation matrix for higher degrees, as the $N$ increases, the matrix becomes more sparse.

**Description of Bernoulli matrix method**

For solving the proposed Volterra integro-differential equations, first, we can approximate the unknown function $y^m(x)$ by Bernoulli matrix as

$$
y^m(x) = A^T B_m(x),
$$

which $A^T = [a_0, a_1, \ldots, a_N]$ is the unknown vector. By integrating Eq. (16), we have

$$
y_i(x) = \sum_{j=0}^{m} A_j^T p^j B(x),
$$

which $A_j^T = [a_j, 0, \ldots, 0], j = 0, 1, \ldots, m - 1$.

Now, by (11), (14), (16), we approximate $f(x)$ and $k(x, s)$ by Bernoulli polynomials and by replacing them and (16), (17) in the Eq. (1), we have

$$
\sum_{i=0}^{m} \sum_{j=0}^{i} A_j^T p^i B(x) = F^T B(x) + B(x) K \int_0^x B^T(s) B(s) ds \sum_{j=0}^{m} p^j A_j
$$

Now we collocate (18) in $N + 1$ nodes

$$
t_i = \frac{2i - 1}{2(N + 1)}, i = 1, 2, \ldots, N + 1
$$

then we have a system of linear algebraic equations of $(N + 1) \times (N + 1)$ degree, with unknown vector $A_m$, by solving this linear system, we find $A_m$, and can approximate the solution of equation (1) as follows
\[ y(x) = \sum_{j=0}^{m} A_j^T p^j B(x) \quad (20) \]

**Convergence Analysis**

In this section, an error analysis will be implied to apparently explain the convergence of the mentioned method. Assume that we approximate the function \( f \) on the interval \([0,1]\) by Bernoulli polynomials as argued in Corollary 3.1. Then the coefficients \( f_n \) decays as follows \( f_n \leq \frac{F_n}{n!} \), where \( f_n \) denotes the maximum of \( f_n \) in the interval \([0,1]\). The above Corollary implies that Bernoulli coefficients are decayed rapidly as decreasing of \( n \). Now we have the following theorem.

**Theorem 6.1.** [1] Suppose that \( f(x) \) be an enough smooth function in the interval \([0,1]\) and be approximated by Bernoulli polynomials as done in Corollary 3.1. With more details assume that \( P_N[f](x) \) is the approximate polynomial of \( f(x) \) in terms of Bernoulli polynomials and \( R_N[g](x) \) is the remainder term. Then, the associated formulas are stated as follows

\[
\begin{align*}
  f(x) &= P_N[f](x) + R_N[f](x) \\
  P_N[f](x) &= \int_0^1 f(x)dx + \sum_{j=1}^{N} B_j(x) \left( f^{j-1}(1) - f^{j-1}(0) \right) \\
  R_N[f](x) &= -\frac{1}{N!} \int_0^1 B_N^N(x-t)f^N(t)dt
\end{align*}
\]

where \( B_n^N(x) = B_N(x-[x]) \) and \([x]\) denotes the largest integer not greater than \( x \).

**Proof.** See [1]. It is clear that the algebraic degree of exactness of the operator \( P_N[\cdot] \) is \( N \).

**Theorem 6.2.** Suppose \( f(x) \in C^\infty[0,1] \) and \( P_N[f](x) \) is the approximate polynomial using Bernoulli method. Then the error bound would be obtained as follows

\[
\|\text{error}(f(x))\|_\infty \leq \frac{1}{N!} B_N f_N
\]

where \( B_N \) and \( F_N \) denote the maximum value of \( B_N(x) \) and \( f_N(x) \) in the interval \([0,1]\), respectively.

**Proof.** By considering \( R_N[f](x) = -\frac{1}{m!} \int_0^1 B_N^N(x-s)f^N(s)dx \) the proof is clear.
Theorem 6.3. Suppose \( k(x, s) \) be a smooth enough function and \( P_N[k](x, s) \) is the approximate polynomial using Bernoulli method. Then the error bound would be obtained as follows

\[
\|\text{error}(k(x, s))\| \leq \frac{1}{(N!)^2} B_N^2 k_{N,N}
\]

where \( B_N \) and \( k_{N,N} \) denote the maximum value of \( B_N(x) \) and \( k^{N,N}(x, s) \) in the interval \([0, 1]\) respectively.

Theorem 6.4. We have Considered \( m = 0 \) and \( c_0 = 1 \) in Eq. (1). Also assume that \( y(x) \) is the exact solution and \( y_N(x) \) is the approximated solutions of (1) with the proposed assumption.

Furthermore, we consider the following hypotheses

1) \( \|y(x)\| \leq \bar{y}, \ \forall x \in I = [0,1] \)
2) \( \|k(x, s)\|_\infty \leq \bar{k}, \forall (x, s) \in I \times I \)
3) \( \bar{k} + e(k) < 1 \)

Then

\[
\|y(x) - y_N(x)\|_\infty \leq \frac{e(f) + e(k)\bar{y}}{1 - (\bar{k} + e(k))}
\]

Where

\[
e(k) = \|\text{error}(k(x, s))\|_\infty = \|k(x, s) - k_N(x, s)\|_\infty, \ \forall (x, s) \in I \times I
\]

\[
e(f) = \|\text{error}(f(x))\|_\infty = \|f(x) - f_N(x)\|_\infty
\]

Proof. Because both of the kernel \( k(x, s) \) and function \( f(x) \) are approximated by Bernoulli polynomials, then the obtained solution is an approximated polynomial in the form of \( y_N(x) \). Our goal is to get an upper bound for the associated error between the exact solution \( y(x) \) and the approximated solution \( y_N(x) \) for the Eq. (1). We have

\[
\|y(x) - y_N(x)\|_\infty = \left\| f(x) + \int_0^x k(x, s)y(s)ds - f_N(x) - \int_0^x k_N(x, s)y_N(s)ds \right\|_\infty
\]

\[
\leq \|f(x) - f_N(x)\|_\infty + \|k(x, s)y(s) - k_N(x, s)y_N(s)\|_\infty
\]

(21)

on the other hand

\[
\|k(x, s)y(s) - k_N(x, s)y_N(s)\|_\infty
\]

\[
= \|k(x, s)y(s) - k(x, s)y_N(s) + k(x, s)y_N(s) - k_N(x, s)y_N(s)\|_\infty
\]

\[
\leq \|k(x, s)\| \|y(s) - y_N(s)\|_\infty + \|k(x, s) - k_N(x, s)\|_\infty \|y(s)\|_\infty
\]
from (21), (22)
\[ ||y(x) - y_N(x)|| \leq \left( e(f) + \tilde{k} + e(k) \right) ||y(s) - y_N(s)||_\infty + e(k)\bar{y} \]

therefore
\[ ||y(x) - y_N(x)|| \leq \frac{e(f) + e(k)\bar{y}}{1 - (\tilde{k} + e(k))} \]

**Computational Complexity**

In this section, we will use the O notation to describe the time complexity of algorithms used in the method. For this purpose, we divided them into three categories. First, the algorithm of producing Bernouli vector, so producing each vector of Eq. (7) requires \( O(N + 1) \), second, the time complexity of the algorithm of collocation of the nodes defined in Eq. (19), is \( O(N + 1) \), and finally, a single solution of linear system of Eq. (18) can be obtained with \( O((N + 1)^2) \) time complexity.

**Illustrative Examples**

To assess the performance of the proposed method, and show the efficiency of this method, we consider three illustrations of Volterra integro-differential equations with the initial conditions. The absolute errors for \( K \) different values are shown in Tables. The RMS error in the solutions:

\[ E = \sqrt{\frac{1}{K} \sum_{i=0}^{K} (y_e(x_i) - y(x_i))^2} \]

is obtained where \( y(x_i) \) is the exact solution and \( y_e(x_i) \) is the approximated solution of integral equation. Examples implemented by Matlab software.

**Example 7.1.** We consider the following Volterra integro-differential equation of forth order
\[ y'''(x) - y(x) = x(1 + e^x) + 3e^x - \int_0^x y(s)ds, \quad 0 \leq x \leq 1 \] (23)
with initial condition $y(0) = 1$, $y'(0) = 1$, $y''(0) = 2$, $y'''(0) = 3$ and the exact solution is $y(x) = 1 + xe^x$. [25]

**Solution.** To solve this example, we approximate $y'''(x)$ by the Bernoulli polynomials of order $N$ as

$$y'''(x) = A_4^T B(x)$$

And, by using initial conditions of Eq. (23) and the operational matrix of integration (15), we have:

$$y(x) = A_4^T p^4 B(x) + A_3^T p^3 B(x) + A_2^T p^2 B(x) + A_1^T p B(x) + A_0^T B(x) \tag{24}$$

which

$$A_3^T = [3 \ 0 \ 0 \ 0 \ 0], \ A_2^T = [2 \ 0 \ 0 \ 0 \ 0], \ A_1^T = [1 \ 0 \ 0 \ 0 \ 0], \ A_0^T = [1 \ 0 \ 0 \ 0 \ 0]$$

Now, we approximate $f(x)$ and $k(x, s)$ by Bernoulli polynomials as stated in section 5, by replacing these approximations and (24) in the (23) and by collocation points

$$t_i = \frac{2i - 1}{2(N + 1)}$$

we solve the linear algebraic equation and achieve $A_4$ vector. The comparison between the absolute error of presented method by $N = 4$ and $N = 8$, and legendre method are shown in Table 1 which shows Bernoulli matrix method is more accurate and also, it can be seen with increasing $N$, error reduces. and the error corresponds with the upper bound error in theorem 6.3.

**Table 1. Absolute error for example 1**

**Example 7.2.** We consider the following Volterra integro-differential

$$y'(x) = 1 - \int_0^x y(s)\,ds, \ 0 \leq x < 1,$$ \tag{25}

with initial condition $y(0) = 0$ and the exact solution is $y(x) = \sin x$. [26]

**Solution.** To solve this example, we approximate $y'(x)$ by the Bernoulli polynomials of order $N$, as
Numerical Approximation Based on the Bernoulli Polynomials for Solving Volterra Integro-Differential of High Order

\[ y'(x) = A_1^T B(x), \quad (26) \]

and, by using initial conditions of (25) and the operational matrix of integration (15), we have:

\[ y(x) = A_1^T P B(x), \quad (27) \]

then, (25) can be rewritten as

\[ A_1^T B(x) = F^T B(x) - B^T(x) K D^T A_1, \quad (28) \]

where

\[ F^T = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \end{bmatrix}, \quad D = \int_0^x B(s) B^T(s) ds, \quad K = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \]

we replace the collocation points into (28), then, we solve the linear algebraic and achieve \( A_1 \) vector. The comparison between the results of presented method for \( N = 4 \) and \( N = 6 \), and Bessel series method are shown in Table 2. The comparison between \( N=4 \) and \( N=6 \) confirms the findings of the first example and shows that by increasing \( N \) and consequently increasing the number of nodes, the error decreases.

**Example 7.3.** We consider the following Volterra integro-differential equation

\[ y'(x) + y(x) = \int_0^x e^{x-s} y(s) ds, \quad 0 \leq x < 1 \]

with initial condition \( y(0) = 1 \) and the exact solution is \( y(x) = e^{-x} \cosh x. \) [9]

**Solution.** To solve this example, we approximate \( y'(x) \) by the Bernoulli polynomials, as

\[ y'(x) = A_1^T B(x), \quad (30) \]

where, \( A_1 \) is the unknown vector. And, by using initial conditions of Eq. (29) and the operational matrix of integration Eq. (16), we have:

\[ y(x) = A_1^T P B(x) + A_0^T B(x), \quad (31) \]

which \( A_0^T = [1 \ 0 \ 0 \ 0 \ 0] \) Now, by replacing (30), (31) in the (29),
\[ A_1^T B(x) + A_1^T P B(x) + A_0 B(x) = B^T(x) K D (A_1 + P^T A_1) \]  

(32)

Now, by collocating points and solving the linear algebraic for \( N = 4 \) and \( N = 6 \) we achieve \( A_1 \) vector. The comparison between the absolute error of presented method, are shown in Table 3 and shows that by increasing \( N \) and consequently increasing the number of nodes, the error decreases.

</table>

**Remark**

It is found that the errors in Bernoulli matrix method solutions get reduced in comparison with the errors in [26], [25]. The matrices \( D \) and \( P \) in Eqs (15), (28) have large numbers of zero elements and they are sparse, hence the present method is very attractive and reduces the CPU time and the computer memory. Also Theorem 6.4 shows the answer is convergent, and as shown in examples the error reduces with increasing \( N \).

**Conclusion**

In this article, we have shown that the Bernoulli matrix method can be employed to solve Volterra integro-differential equations. One of the advantage of this method is that the numerical solution of these equations can be converted into system of linear algebraic equations. The numerical results are used to demonstrate the application of this method. Considering the ease of working with high-order Bernoulli polynomials and the low error, This method is superior to other methods.

It is only with some minor modifications that the proposed method can be extended to systems of Volterra integro-differential equations.
